

## Harmonic perturbation

As an application of time-dependent perturbation theory let us consider a perturbation that is turned on at  $t=0$  and is subsequently monochromatic in time. The perturbation acts on a system whose Hamiltonian is  $H'$ . Such a model is relevant for describing an atom that interacts with a weak electromagnetic field. The explicit formula for the perturbation is

$$H'(\vec{r}, t) = \begin{cases} 0, & t < 0 \\ f\vec{l}'(\vec{r}) \sin \omega t, & t \geq 0 \end{cases}$$

Using the expression for the probability amplitudes obtained in the previous lecture, namely

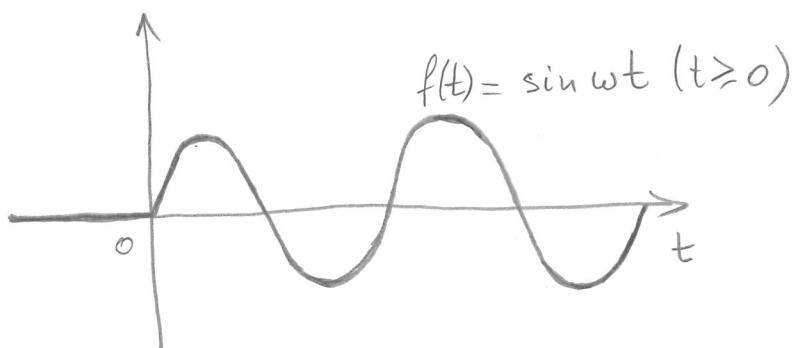

$$C_{fi}^{(1)} = \frac{\vec{f}\vec{l}'_{fi}}{i\hbar} \int_0^t e^{i\omega_f i t'} f(t') dt'$$

we get (we will drop the (1) superscript for simplicity)

$$\begin{aligned} C_{fi}(t) &= \frac{\vec{f}\vec{l}'_{fi}}{i\hbar} \int_0^t e^{i\omega_f i t'} \left( \frac{e^{i\omega t'} - e^{-i\omega t'}}{2i} \right) dt' = \\ &= -\frac{\vec{f}\vec{l}'_{fi}}{2\hbar i} \left[ \frac{e^{i(\omega_f + \omega)t} - 1}{\omega_f + \omega} - \frac{e^{i(\omega_f - \omega)t} - 1}{\omega_f - \omega} \right] \end{aligned}$$

If we use the relation we can rewrite it as

$$C_{fi}(t) = -\frac{\vec{f}\vec{l}'_{fi}}{\hbar} \left[ \frac{e^{i(\omega_f + \omega)t/2} \sin \frac{(\omega_f + \omega)t}{2}}{\omega_f + \omega} - \frac{e^{i(\omega_f - \omega)t/2} \sin \frac{(\omega_f - \omega)t}{2}}{\omega_f - \omega} \right]$$

$f(t) = \sin \omega t \quad (t \geq 0)$

for the perturbation is

$c_{fi}$  becomes large when  $\omega \approx \pm \omega_{fi}$  (resonant frequency)

In the case  $\omega \approx +\omega_{fi}$   $E_f > E_i$  and the system absorbs energy and "jumps" to a higher energy level  $E_f = E_i + \hbar\omega$

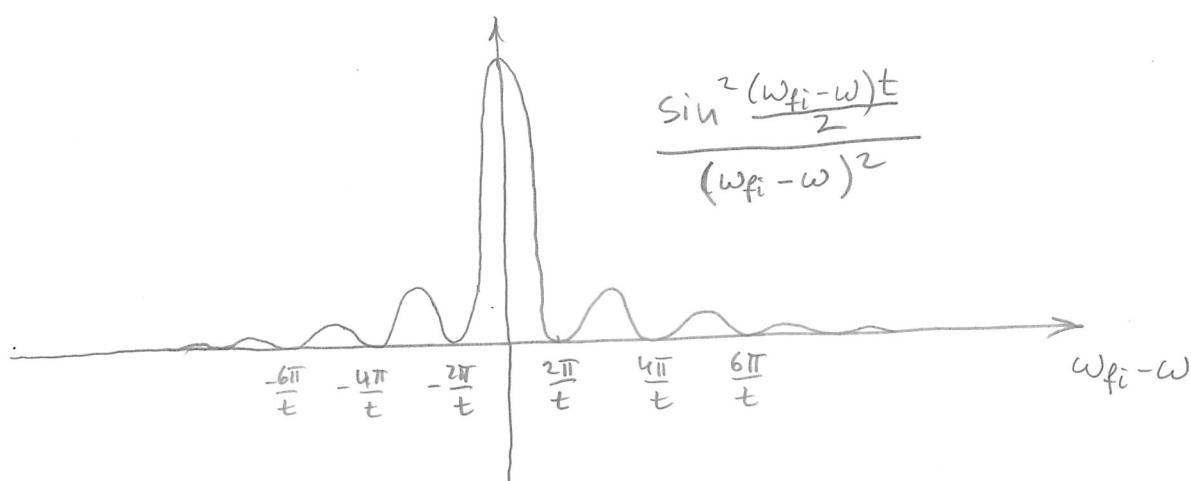

In the case  $\omega \approx -\omega_{fi}$   $E_f < E_i$  and we can say that the perturbation induces a decay in energy  $E_f = E_i - \hbar\omega$

The decay process is stimulated by a photon of the same frequency in the perturbation field (stimulated emission)

Let us consider the case when  $\omega_{fi} > 0$ . Under this condition the second term in the expression for  $c_{fi}(t)$  above dominates. The corresponding probability of transition is then

$$P_{fi} = |c_{fi}|^2 = \frac{|\mathcal{H}_{fi}^1|^2}{t^2(\omega_{fi} - \omega)^2} \sin^2 \left[ \frac{(\omega_{fi} - \omega)t}{2} \right]$$

From the sketch above it is evident that the states falling in the interval  $|\hbar\omega_{fi} - \hbar\omega| = |E_f - (E_i + \hbar\omega)| \leq \frac{2\pi\hbar}{t} \approx \Delta E$  have the greatest probability of being

excited, after the perturbation has acted for time  $t$ . Hence, the above inequality provides the uncertainty in the energy (after time  $t$ ) that will be observed:

$$\Delta E \approx \frac{\hbar}{t} \quad E_f \approx E_i + \hbar\omega \pm \Delta E$$

Our analysis has yielded the conservation of energy within the uncertainty.

Let us now consider long-time evolution. The expression for  $P_{fi}$  in the limit  $t \rightarrow \infty$  (or, alternatively,  $\omega \rightarrow \infty$ ) becomes resonant at  $\omega = \pm \omega_{fi}$  and, in fact, approaches a delta function:

$$\frac{1}{\pi} \lim_{t \rightarrow \infty} \frac{\sin^2 dt}{d^2 t} = \delta(\omega)$$

$$\left( \int_{-\infty}^{+\infty} \frac{\sin^2 dt}{d^2 t} dd = \int_{-\infty}^{+\infty} \frac{\sin^2 dt}{d^2 t} ddt = \int_{-\infty}^{+\infty} \frac{\sin^2 x}{x^2} dx = \pi \right)$$

$$P_{fi} = \frac{|\mathcal{H}_{fi}|^2 t}{\hbar^2 (\omega_{fi} \mp \omega)^2} \sin^2 \left[ \frac{(\omega_{fi} \mp \omega)t}{2} \right] \rightarrow \frac{\pi t |\mathcal{H}_{fi}|^2}{2 \hbar^2} \delta(\omega_{fi} \mp \omega)$$

The corresponding transition probability rate is

$$W_{fi} = \frac{d P_{fi}}{dt} = \frac{\pi}{2 \hbar^2} |\mathcal{H}_{fi}|^2 \delta(\omega_{fi} \mp \omega)$$

In the formulae for  $W_{fi}$  and  $P_{fi}$  the presence of the delta function constitutes the fact that in the long-time limit the Fourier transform of the perturbation becomes sharply peaked around the frequency of the perturbing field. Thus, the system will only see a single frequency. Since the uncertainty in energy,  $\frac{\hbar}{t}$ , vanishes in this limit, the argument of the delta function is also a manifestation of the conservation of energy.

In the short-time approximation, when  $(\omega_{fi} - \omega)t \ll 1$

the expression for  $P_{fi}$  may be expanded into a Taylor series in  $t$ :

$$P_{fi} = \frac{t^2 |\mathbf{f}\ell'_{fi}|^2}{4t^2} \quad \text{and then} \quad W_{fi} = \frac{t |\mathbf{f}\ell'_{fi}|^2}{2t^2}$$

At early times the rate at which transitions to the final state occur grows linearly with time.
